

Apply Last Frame

File path: Assets/UIAnimationToolkit/Editor/Animation/Anim_ApplyLastFrame.cs

Menu: Tools > UI Animation Toolkit > Animation > Apply Last Frame

Overview

Read the final stored value of each supported numeric curve in the active clip and apply it to the corresponding scene component. This sets scene end-state values without rewriting the clip. It processes supported clip bindings, not just selected keys.

How to use

1. Select the animated object/root in the Hierarchy and open its clip in the Animation window. Ensure the bindings resolve under that root.
2. Open Apply Last Frame and verify Current Clip. The current interface contains this read-only field and an Apply button.
3. Click Apply Last Frame, then inspect the scene properties and pose directly.
4. Use Undo to revert if needed. Save scene or Prefab changes deliberately after checking the result.

Interface and parameters

Interface schematic based on the active OnGUI implementation.

Control / parameter	Description
Current Clip	Read-only clip detected from the Animation window.
Apply Last Frame	Apply supported last-key values to scene objects. The button is disabled when no clip is detected.

Example

If a position curve’s final stored value is 120 and an alpha curve’s final stored value is 0, the tool attempts to write those values to the resolved scene components. It leaves the original clip keys in place.

Notes

- The source uses each curve's last stored key value, rather than sampling the entire Animator graph at a single final time. Curves may end at different times.
- Object-reference curves are skipped. Unsupported fields and unresolved paths cannot be applied. A scene root must be available even though the button's enabled state only checks for a clip.
- This revision contains helper code for a richer preview/status interface, but its active OnGUI does not display it. Do not expect an in-window Current/Final table or visible result counter.
- Quaternion-related handling is approximate; inspect complex rotations rather than assuming an exact final pose.
- Undo is recorded for affected objects. This command does not create a new clip or reduce keyframe counts; use Keep Last Frame Only for a one-key clip.
- Preview/playback can drive the same scene properties again. Inspect the intended saved state outside preview before relying on it.
